

Scripting Assessment Report

The development of PhaviconPhisher

Jack Laundon

CMP320: Advanced Ethical Hacking

2024/25

Note that Information contained in this document is for educational purposes.

Abstract

Phishing attacks are one of the most common forms of cybercrime, costing large sums in damages across the globe. Phishing websites make up over half of phishing attempts, trying to entice the user to enter sensitive credentials, with stolen credentials being the most common cause of a data breach. If a data breach occurs, the affected company could be required to pay millions in reparations. Therefore, it is vital to be able to spot phishing websites. PhaviconPhisher, a script that detects phishing websites using their favicon, was developed to aid in detecting phishing websites.

The development of the program was split into six main stages: taking user input, processing the input, searching Shodan for websites using the same favicon, filtering out legitimate websites, cleaning the program up, and Docker integration. The program was developed by PEP8 and PEP257 standards. Each section of the program was tested to ensure proper functionality, with the final results output to the user: a list of suspicious websites written to a file and a message stating whether or not the given address is likely a phishing site.

While the script has limitations, such as API tier dependency, it could reduce the likelihood of a successful phishing attack by simplifying the identification of phishing sites. This, in turn, could reduce the number of data breaches. If the script were to be expanded, the VirusTotal API could be used to search VirusTotal for URLs, adding another test to find malicious websites.

1 INTRODUCTION

1.1 BACKGROUND

Phishing attacks, where an attacker impersonates a trustworthy organisation to attempt to steal credentials, are one of the most common forms of cybercrime, with over \$2.7 billion (£2.03 billion) in damages accrued in 2022 (Information Commissioner's Office, n.d). In 2024, there were at least 250,000 reported phishing attempts per month. (Anti-Phishing Working Group, 2025). As displayed in **Figure 1**, there was a slight upward trend in phishing attacks in 2024.

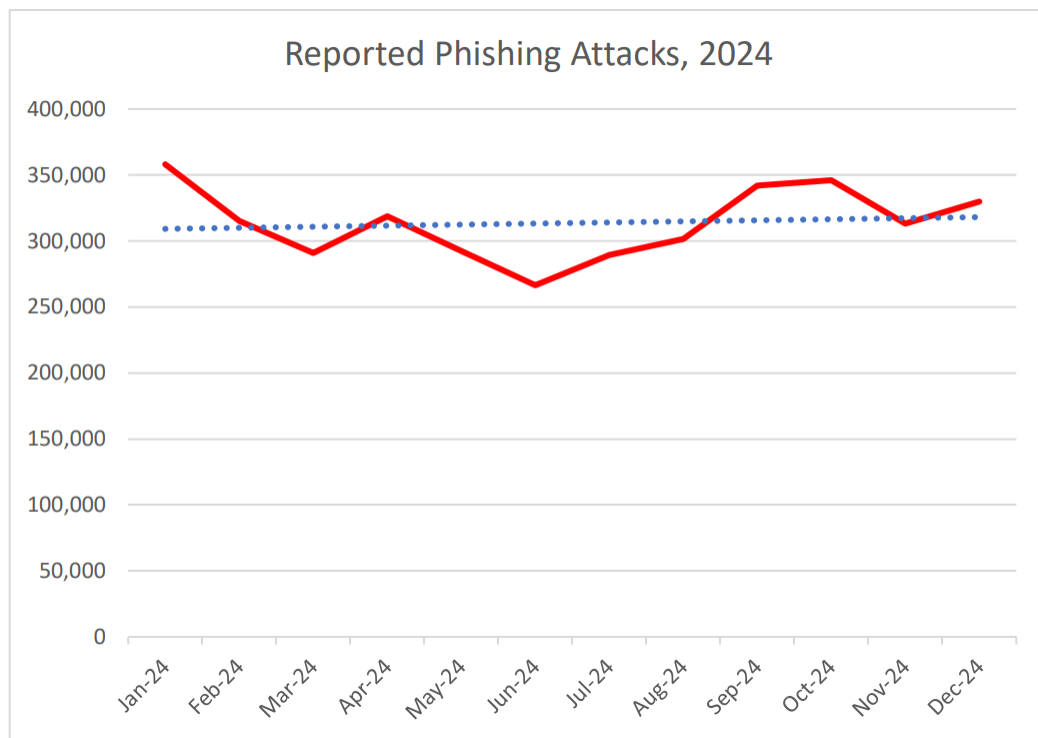

Figure 1 - Phishing trends in 2024 (Anti-Phishing Working Group, 2025)

While phishing attacks can take many forms, one of the most common is phishing websites. Phishing websites attempt to mimic legitimate websites, often copying the layout, to entice users into entering sensitive credentials into the website. On average, nearly 1.5 million such websites are deployed every month (Griffiths, 2025). Over 50% of phishing interactions in 2024 involved a phishing website (Coker, 2025). With compromised login details being the number one cause of data breaches (Griffiths, 2025), and the worldwide expense of a data breach costing \$4.88 million (£3.67 million) on average (IBM, n.d), it is imperative that companies take action to mitigate against and reduce the impact of phishing attacks.

Despite the advancement in awareness around phishing websites (Baker & Cartier, n.d), attackers are still successful in luring users to give away their credentials. Users are often fooled by the appearance of such websites, as phishing websites are often exact replicas of legitimate websites, going as far as using the same favicon – a small image used to represent a webpage, akin to a thumbnail icon. While it is possible

to detect a phishing site using the favicon (Kopriva, 2021), many computer users do not possess the technical knowledge to do this. This prompted the development of *PhaviconPhisher*, a Python script that automates the process of using the favicon to determine whether a given website is likely phishing.

1.2 AIM

This project aims to develop a script that takes a web/IP address from a user and detects whether it is a phishing site. To meet this aim, the following sub-aims must be completed. The program must:

- Accept and validate an IP/web address from the user
- Hash the favicon of the given website
- Search the hash on Shodan
- Filter Shodan results to return only suspicious websites
- State whether the given website is likely a phishing site
- Run on any system without manual dependency installation

2 METHODOLOGY

2.1 OVERVIEW OF METHODOLOGY

The creation of this script involved six main stages, outlined in the table below:

Table 1 - The stages involved in the methodology

Stage	Description
User Input	Taking and validating input from the user.
Processing URL	Testing if the given address can be reached and hashing the favicon if successful.
Shodan Searching	Searching the favicon hash on Shodan.
Results Filtering	Filtering results to contain suspicious entries from the Shodan results.
Cleaning Up	Splitting functions into files and linking everything together through one main file
Docker	Creating a Docker container to run the script

Each stage was programmed by the Python Enhancement Proposal (PEP) 8 Python coding convention to ensure readable and consistent code. PEP 8 is the official style convention for Python (Finer, 2025), guiding constructs such as naming standards, format, or code comments (Finer, 2025). As well as PEP 8, the PEP 257 style guide was used when writing docstrings (Goodger & van Rossum, 2001). Docstrings are designed to explain what each module/function does, and as such, it is vital to ensure that these are clear and understandable. Therefore, PEP 257 was utilised, as this convention provides guidance to keep docstrings consistent and readable. This script was entirely created in the *Visual Studio Code* editor, using *Visual Studio Code version 1.99*. Several libraries were used to support the development of this script, some of which were external and required installation. The external libraries used for this program are as follows:

- *Shodan*
- *Requests*
- *Colorama*
- *Mmh3*

The following subsections provide an overview of each section of the methodology.

2.2 USER INPUT OVERVIEW

The first phase of development was the user input stage. This involved ensuring that the user input was handled correctly and incorrect input was not passed further into the script. Regular expressions (Regex) were first employed to sanitise the user input, before ensuring that the entered address had a valid HTTP/HTTPS scheme. The libraries used in this stage are displayed below, in **Table 2**.

Table 2: Libraries used for user input.

Library	Use
Re	Enabled the use of Regex to validate and sanitise user input
Urllib	Used to validate user input

2.3 PROCESSING URL OVERVIEW

Following on from the implementation of the user input section, the next step was to process the validated URL. This module first used the *requests* library to send a request to the target website and return the status code. If the website could be reached, the *requests* library was then used to download the favicon, which was then hashed into MurmurHash(MMH) format. **Table 3** displays the libraries used during this stage.

Table 3: Libraries used when processing the URL

Library	Use
Re	Enabled the use of Regex to split strings
Base64	Base64 encoding was used on the favicon
Requests	Used to download the favicon
Mmh3	Used to encode the favicon in the necessary format

2.4 SHODAN SEARCHING OVERVIEW

The next stage of development was the implementation of the Shodan search. Shodan, a search engine containing information about devices connected to the internet, was employed to search for all websites using the same favicon as the website entered by the user. The Shodan API was used to search Shodan for any websites using the favicon hash. The libraries used during this stage are displayed in the table below.

Table 4: Libraries used to search Shodan

Library	Use
Os	Operating System library used to retrieve the API key
Shodan	Enables the use of the Shodan API to search Shodan

2.5 RESULTS FILTERING OVERVIEW

The results filtering stage of the script development was to program a method of filtering out legitimate websites using the same favicon, ensuring that only suspicious websites were returned. This was done by comparing any websites found to the following criteria:

- Running on an unusual port
- Suspicious domain characteristics:
 - Suspicious Top-Level Domain (TLD)
 - Very short domain name
 - Many hyphens in the URL
 - Many subdomains
 - Suspicious keywords in the address
- No Secure Socket Layer (SSL) certificate
- A self-signed SSL certificate

If a website matched any of these criteria, the website was added to a list containing suspicious websites returned by Shodan. If the address entered by the user was found to be in this list, the script displayed a message on the console screen warning that it is likely a phishing website. The libraries used to process the results are evidenced in the table below.

Table 5: Libraries used when processing results

Library	Use
Re	Regex was used to search for suspicious keywords in a returned domain
Urllib	Used to parse and separate a URL from a port
Collections	Used to access the default dict structure

2.6 CLEANING UP

The penultimate stage of the development was to “clean up” the script. This involved splitting each stage of the program into different files and linking everything together, creating a help option, and creating a command line interface (CLI), displaying the name and author of the program. The libraries used in this stage are displayed in **Table 6**.

Table 6: Libraries used when cleaning up the script

Library	Use
Argparse	Used to parse arguments from the command line to provide the help option
Colorama	Used to style the displayed program name

2.7 DOCKER

The final stage of development was integrating the script with Docker. Docker is a tool used to build “containers” – isolated environments in which code can be run. These containers hold everything required for the script to run, such as the necessary dependencies (Docker, n.d). Integrating the script within a Docker container ensures that the script can be run on any system or machine, regardless of what is installed on the host machine, as everything needed for the script is held within the Docker container (Docker, n.d). The only tool used for this was *Docker version 4.40.0*.

3 PROGRAM AND DEVELOPMENT

3.1 PROGRAM AND DEVELOPMENT OVERVIEW

As stated in **Section 2 – Methodology**, the development of *PhaviconPhisher* was split into six main stages. This was done sequentially, with each phase developed until fully complete before the next phase commenced. The development of this program is outlined in the following sub-sections.

3.2 USER INPUT

To begin the development of *Phavicon Phisher*, the user input section of the script was focused. The user input had to be validated and sanitised, to ensure that the input was in the correct format to pass into the rest of the program.

3.2.1 Sanitise_address()

The first function to be developed was the `sanitise_address()` function. The `sanitise_address()` function takes one parameter – the user input – and sanitises it. This is to ensure that no unwanted input is entered into the program. Usually, when validating input, one of the main priorities is protecting against Cross-Site Scripting (XSS), which is where malicious JavaScript is entered and executed on a web page. However, as this program does not render anything on a web page, XSS did not need to be considered. Similarly, as this program does not interact with databases, SQL injection did not warrant attention. Another security concern to consider is command injection. As is described in **Section 3.4 – Shodan Searching**, the `operating system` library is used to retrieve the Shodan API key. Typically, command injection attacks must be considered when the `OS` library is used, as this module directly interacts with the operating system. However, as is described in **Section 3.4 – Shodan Searching**, the `OS` library is only used to read the API key, and therefore, command injection attacks were not a concern, as user input is not passed into the `OS` module. Instead, the main concern was to ensure that the supplied address was a valid IP/web address. This was done by removing any trailing or leading whitespace or slashes, as evidenced by **Figure 2**.

```
def sanitise_address(address):  
    """  
    Sanitise entered address to remove whitespace and trailing slashes.  
    Arguments:  
    | address - the website address entered by the use  
    Returns:  
    | address - the sanitised version of the entered address  
    """  
    #removes trailing or leading whitespace  
    address = address.strip()  
    #removes trailing slashes  
    address = re.sub(r'/*$', '', address)  
    return address
```

Figure 2 - `sanitise_address` function

This uses the “strip” pre-defined function to remove any whitespace, and regex to remove any trailing slashes. This ensured that the given address would not cause any errors when passed into other functions.

3.2.1.1 Sanitise_address() Test Case

To test the sanitise_address function, the following test case was carried out. The objective of the test case was to ensure that the program removes any trailing or leading whitespace from user input and removes any trailing slashes. The results of the test case are displayed in **Table 7**, with a demonstration of the test displayed in **Figures 3-6**.

Table 7 - Test Case #001

Test Case ID	Objective	Input	Expected Output	Actual Output
#001	Verify Input Sanitisation	www.example.com///	<u>www.example.com</u>	www.example.com
		127.0.0.1///	127.0.0.1	127.0.0.1
		www.example.com:80//	www.example.com:80	www.example.com:80
		127.0.0.1:80//	127.0.0.1:80	127.0.0.1:80

```
Enter a website address or IP address:
www.example.com///
www.example.com
```

Figure 3 - Testing www.example.com///

```
Enter a website address or IP address:
127.0.0.1///
127.0.0.1
```

Figure 4 - Testing 127.0.0.1///

```
Enter a website address or IP address:
www.example.com:80//
www.example.com:80
```

Figure 5 - Testing www.example.com:80//

```
Enter a website address or IP address:
127.0.0.1:80//
127.0.0.1:80
```

Figure 6 - Testing 127.0.0.1:80//

As displayed above, the input sanitisation function returned the user input with no trailing slashes or whitespace, so this function was deemed completed. The completed function can be viewed in **Figure 1**.

3.2.2 Is_valid_address()

After the address was cleaned by the sanitise_input function, the next stage was to test if the address met the correct format for an IP address or web address. Regex was employed to test the supplied address for either an IP address or a web address formatting. This was carried out by first writing an expression to test for an IP address format, displayed below in **Figure 7**.

```
#regex to validate IP address format
ipv4_pattern = re.compile(
    #checks for the inclusion of http(s) (optional)
    r"^(http[s]?://)?"
    #regex pattern for IP address
    r"(\d{1,3}\.){3}\d{1,3}"
    #checks for the inclusion of a port (optional)
    r"(:\d{1,5})?$"
)
```

Figure 7 - regex for IP addresses

As demonstrated, the regex tests for the inclusion of an HTTP/HTTPS scheme, but will not throw an error if it is not there. As denoted by the question mark, this is an optional part of the address. The port is also an optional part of the address. Crucially, the line:

```
"r"^(\d{1,3}\.){3}\d{1,3}"
```

Tests for the correct IP address format. Specifically, the `"(\d{1,3}\.){3}\d{1,3}"` portion tests for three identical portions of an IP address – a string with between one and three digits separated by a full stop, and a final set of digits without a full stop after it (e.g. 192.168.1.10). This ensures that the IP address is validated correctly. The HTTP/HTTPS scheme and port are checked even though they are optional, so that the program runs smoothly regardless of HTTP(S) or port inclusion.

Conversely, the program also accepts web addresses (such as www.example.com). Displayed in **Figure 8** is the regex used to ensure that valid web addresses were entered into the program.

```
domain_pattern = re.compile(
    #checks for the inclusion of http(s) (optional)
    r"^(http[s]?://)?"
    #regex pattern for domain name
    r"([a-zA-Z0-9-]+\.[a-zA-Z]{2,})(/[\w\-\./]*)*"
    #checks for the inclusion of a port (optional)
    r"(:\d{1,5})?$")
```

Figure 8 - Regex to validate web addresses

As above, the HTTP(S) scheme and port are optional, while the actual address pattern must be matched before the program can continue. The regex ensures that the domain name portion matches standard address formats (e.g. www.example.com, www.example/example.com, or www.example-example/example1.com). The function then returned true or false depending on if the provided address was valid, as seen in **Figure 9**.

```
return (
    ipv4_pattern.match(address)
    or domain_pattern.match(address)
)
```

Figure 9 - The `is_valid_address` function returns

3.2.2.1 `is_valid_address()` Test Case

To test this function, a while loop was introduced to block the script from proceeding until the address supplied was deemed valid. This can be seen in **Figure 10**.

```
while not is_valid_address(address):
    print("Invalid address format. Please enter a valid domain or IP.")
    address = input("Enter a website address or IP address: \n")
    sanitised = sanitise_address(address)
print("Valid address")
```

Figure 10 - Testing for a valid address

The test case for this function can be examined below in **Table 8**.

Table 8: Test Case #002

Test Case ID	Objective	Input	Expected Output	Actual Output
#002	Ensure address validation	192.1345.123-	Invalid address format. Please enter a valid domain or IP	Invalid address format. Please enter a valid domain or IP

Valid Address
```

Figure 14 - Testing web addresses

As seen in **Table 8**, and **Figures 11-14**, the program behaved as expected, rejecting and approving the appropriate inputs. As this function functioned as intended, it was deemed complete. The full function is displayed in **Figure 15**.

```

def is_valid_address(address):
    """
    Validate whether the given address is a valid IP address or domain name.
    The function uses regex to match the input.

    Parameters:
    | address(str): the address string to evaluate
    Returns:
    | re.match | None: A match if the address is valid, otherwise none.
    """

    #regex to validate IP address format
    ipv4_pattern = re.compile(
        #checks for the inclusion of http(s) (optional)
        r"^(http[s]?://)?"
        #regex pattern for IP address
        r"(\d{1,3}\.){3}\d{1,3}"
        #checks for the inclusion of a port (optional)
        r"(:\d{1,5})?$"
    )

    #regex to validate url format
    domain_pattern = re.compile(
        #checks for the inclusion of http(s) (optional)
        r"^(http[s]?://)?"
        #regex pattern for domain name
        r"([a-zA-Z0-9-]+\.[a-zA-Z]{2,})(/[\w\~/*]*)?"
        #checks for the inclusion of a port (optional)
        r"(:\d{1,5})?$"
    )

    return (
        ipv4_pattern.match(address)
        or domain_pattern.match(address)
    )

```

Figure 15 - *Is_valid_address()* function

3.2.3 Ensure_scheme()

Following on from input validation, the next step was to ensure that each address entered by the user was prefixed with HTTP/HTTPS. This is due to the use of the *requests* library, further defined in **Section 3.3 – Processing URL**. The *requests* library requires input to have an HTTP(S) scheme to function, so it was vital that this scheme was always present on an address the user entered. To perform this, the *ensure_scheme* function was created. This function utilises the *urlparse* module from the *urllib* library to parse the address supplied. The *urlparse* module checks for a scheme, as shown in **Figure 16**, and adds the default HTTP scheme (HTTP://) to the address if it is not provided. The module checks for the existence of a scheme or a network location (netloc), which includes the domain name and port number (Python Software Foundation, 2025). The script must check for an absence of both a scheme and a netloc to ensure that the address is correctly parsed and that a scheme is added when necessary.

```

parsed = urlparse(address)
if not parsed.scheme or not parsed.netloc:
    return f"http://{address}"
return address

```

Figure 16 - Parsing the address for a scheme

This ensures that the address passed into the *requests* function always matches the expected input.

3.2.3.1 *Ensure_scheme()* Test Case

To verify that this function returns the desired result, the function was called with the final value printed out to the screen. This allowed for confirmation that the HTTP scheme is only being added when necessary. The test case for this is outlined in the table below, with evidence of the test case shown in **Figures 17 and 18**.

Table 9: Test Case #003

Test Case ID	Objective	Input	Expected Output	Actual Output
#003	Verify HTTP Scheme	www.example.com	http://www.example.com	http://www.example.com
		https://www.example.com	https://www.example.com	https://www.example.com
		http://www.example.com	http://www.example.com	http://www.example.com

```

Figure 18 - Testing schemes

As seen above, each address without a scheme was supplied a scheme, and each address with a scheme was left untouched, completing the `ensure_scheme` function. The full function can be seen in **Figure 19**.

```

def ensure_scheme(address):
    """
    Ensures the address has a scheme (http or https).
    If not, defaults to http.
    Arguments:
    | address - the website address entered by the use
    Returns:
    | address - the address with an appropriate scheme
    """
    #checks for a scheme, and adds http:// if none is found
    parsed = urlparse(address)
    if not parsed.scheme or not parsed.netloc:
        return f"http://{address}"
    return address

```

Figure 19 - `Ensure_scheme()` function

3.2.4 Get_address()

Once the user input functions were complete, a “main” function was required to connect all the functions. This function was called “`get_address()`”. This function collects the address from the user and handles all the function calls required for the user input stage: the input is sanitised, validated, and then returned. The function is displayed and can be viewed in **Figure 20**.

```
def get_address():
    """
    Gets the target address from the user.
    Validates and processes it through reach_address.
    Returns:
        address
        returns the address entered by the user after sanitisation and validation
    """
    address = input("Enter a website address or IP address: \n")
    sanitised = sanitise_address(address)

    #input validation
    while not is_valid_address(sanitised):
        print("Invalid address format. Please enter a valid domain or IP.")
        address = input("Enter a website address or IP address: \n")
        sanitised = sanitise_address(address)
    print("Valid Address")
    address = ensure_scheme(sanitised)
    print(address)
    return f"{address}/favicon.ico"
```

Figure 20 - Get_address()

As displayed above, the address is returned with the suffix “/favicon.ico”. This is the location of the favicon on most websites (e.g. www.example.com/favicon.ico). To demonstrate this, **Figure 21** displays the favicon of YouTube, found at <https://youtube.com/favicon.ico>.

Figure 21 - YouTube favicon

3.2.4.1 Get_address() Test Case

The testing of this function focused on the connection of all functions. The test would be considered a success if all functions work correctly; the final address output should have no trailing whitespace or slashes and should be prefixed with an HTTP(S) scheme.

Table 10: Test Case #004

Test Case ID	Objective	Input	Expected Output	Actual Output
#004	Test the user input stage end-to-end	www.example.com//	http://www.example.com	http://www.example.com
		Wwwexamplecom///	Invalid address format. Please enter a valid domain or IP.	Invalid address format. Please enter a valid domain or IP.
		127.0.0.1//	http://127.0.0.1	http://127.0.0.1
		1234jc.01.234.0	Invalid address format. Please enter a valid domain or IP.	Invalid address format. Please enter a valid domain or IP.

		127.0.0.1:80	http://127.0.0.1:80	http://127.0.0.1:80
		https://127.0.0.1:80	https://127.0.0.1:80	https://127.0.0.1:80
		http://127.0.0.1:80	http://127.0.0.1:80	http://127.0.0.1:80
		www.example.com:80//	http://www.example.com:80	http://www.example.com:80
		www.example.com:80	http://www.example.com:80	http://www.example.com:80
		https://www.example.com:80	https://www.example.com:80	https://www.example.com:80
		http://www.example.com:80	http://www.example.com:80	http://www.example.com:80
		http://www.example.com	http://www.example.com	http://www.example.com
		https://www.example.com	https://www.example.com	https://www.example.com

As displayed in **Figures 22 and 23**, all expected outputs matched the actual output, confirming that all functions were connected and operating correctly. This means that the address returned by this module is in the correct format to be passed into the *requests* module, which will be discussed in **Section 3.3.1 – Reach_Address()**. As the address needed no further modification to ensure the correct formatting to be passed further into the program, this concluded the user input stage of development. The fully completed function can be viewed in **Figure 20**.

Figure 23 - End-to-end user input testing

3.2.5 User Input Summary

In summary, the user input module takes an IP/website address from the user and formats it correctly, to allow the address to be successfully passed further into the script. Each function in the module performs a different task to ensure that the address is correctly formatted. This was crucial to the aim of identifying phishing websites, as the address format returned by the module had to match what the rest of the script expected to function properly; if the address was not properly formatted, the website's favicon may not be found. If the favicon is not found, this could provide inaccurate results, thus, it was vital to ensure that the entered address is formatted correctly. The test cases outlined above confirm that each function successfully performs its task and ensures that the returned address reliably and consistently matches the expected format, thus completing the objective of taking and validating user input. **Table 11** contains a summary of each of the functions.

Table 11: User Input Functions

Function	Purpose
Sanitise_address()	Removes trailing/leading whitespace and trailing slashes of the entered address
Ensure_scheme()	Ensures that the entered address has an HTTP(S) scheme
Is_valid_address()	Tests whether the entered address meets the correct IP/website address format
Get_address()	Main function for this module that takes the user input and passes it into the rest of the functions in the module before returning the correctly formatted address

3.3 PROCESSING URL

Following the completion of the user input module of the program, the next logical step was to develop a module that processed the sanitised and validated user input. The purpose of this module is to test the target URL for connectivity and stop the program if the website cannot be reached. If the URL can be reached, the favicon is downloaded and hashed.

3.3.1 Reach_address()

The first function developed in the processing URL stage was the `reach_address()` function. This function takes the address returned from the previously described `get_address()` function and attempts to reach the address using the `requests` library. The `requests` module attempts to connect to the target URL and returns the status code. If the status code returned 200 (OK), the website could be connected to, and the favicon could be found. If a status code returned anything other than 200, the script returns with the error message "Address could not be reached". When attempting to connect to the website, a timeout option of 10 seconds was added to the request. This was to ensure that the script did not "hang" indefinitely if it could not connect to the website. This can be seen in **Figure 24**.

```
def reach_address(web_address):  
    """  
    Attempts to reach the given address.  
    If the address is not reached within 10 seconds, the function  
    Returns:  
    | true if the website can be reached, false if it cannot.  
    """  
  
    try:  
        response = requests.get(web_address, timeout=10)  
        #returns true if the status code is 200 i.e. the website is  
        return response.status_code == 200  
    except requests.exceptions.RequestException:  
        print("Address could not be reached")  
        #returns false if the website cannot be reached  
        return False
```

Figure 24 - Reach_address()

As displayed, this function will return true if the status code is 200, and false in all other situations.

3.3.1.1 Reach_address() Test Case

To test the `reach_address()` function, different addresses were passed into this function to verify that the correct status codes were being returned, with the status code printed each time. Some addresses existed, and some did not. The test case below contains the result of testing the `reach_address()` function, with the results further displayed in **Figures 25-28**.

Table 12: Test Case #005

Test Case ID	Objective	Input	Expected Output	Actual Output
--------------	-----------	-------	-----------------	---------------

#005	Verify that the correct status codes are being returned.	Bbc.co.uk	200	200
		bbc.co.uk/my-account	404 Website could not be reached. Ensure you have a valid network connection	404 Website could not be reached. Ensure you have a valid network connection
		Youtube.com	200	200
		Youtube.com/my-account	404 Website could not be reached. Ensure you have a valid network connection	404 Website could not be reached. Ensure you have a valid network connection

```
http://bbc.co.uk
200
```

Figure 25 - Testing bbc.co.uk

```
http://bbc.co.uk/my-account
404
Website could not be reached. Ensure you have a valid network connection
```

Figure 26 - Testing bbc.co.uk/my-account

```
http://youtube.com
200
```

Figure 27 - Testing youtube.com

```
http://youtube.com/my-account
404
Website could not be reached. Ensure you have a valid network connection
```

Figure 28 - Testing youtube.com/my-account

As demonstrated, the addresses that exist return 200, while the addresses that don't exist return 404 and "Website could not be reached. Ensure you have a valid network connection". This ensures that the script will only continue if the website is found. The full function is displayed in **Figure 24**.

3.3.2 Get_hash()

Once it was confirmed that the script would only proceed if the target website were found, the hashing function had to be developed. The purpose of this function was to download and hash the website's favicon. First, the *requests* function was used to download the favicon, as demonstrated in **Figure 29**.

```

response = requests.get(url, timeout=10)
#if the response code is 200 (the favicon was reached)
if response.status_code == 200:
    #saves the favicon to a file
    with open("favicon.ico", 'wb') as file:
        file.write(response.content)

```

Figure 29 - Downloading the favicon

As seen above, the status code is again checked for more validation. If the code is 200, the favicon is downloaded to a file called “favicon.ico”. The favicon had to be hashed in a way that allowed the hash to be passed into *Shodan*, which meant using the “MurmurHash” format. To hash it in this way, the *mmh3* library was used. **Figure 30** contains the code used at this stage of development to hash the favicon.

```

with open("favicon.ico", "rb") as file:
    image = file.read()
    fav_hash = mmh3.hash(image)
    #outputs the hash
    print(f"The favicon hash is: {fav_hash}")
    return fav_hash

```

Figure 30 - Code to hash the favicon

3.3.2.1 *Get_hash()* Test Case 1

To test the function, the following test case was used. The expected outputs were obtained using a Shodan favicon hash generator (kmsec-uk, 2024) as displayed in **Figures 31-34**.

Figure 33 - https://google.com/favicon.ico

The test case is outlined in the table below.

Table 13: Test case #006

Test Case ID	Objective	Input	Expected Output	Actual Output
#006	Confirm that the favicons are being hashed correctly	Reddit.com	-1640178715	2072632434
		Bbc.co.uk	111446429	-1457664737
		Youtube.com	1179099333	-1641418682
		Google.com	708578229	-1846423585

As stated above, and displayed below in **Figures 35-38**, the expected output did not match the actual output.

```
reddit.com
The favicon hash is: 2072632434
```

Figure 35 - Reddit hash

```
bbc.co.uk
The favicon hash is: -1457664737
```

Figure 36 - BBC hash

```
youtube.com
The favicon hash is: -1641418682
```

Figure 37 - YouTube hash

```
google.com
The favicon hash is: -1846423585
```

Figure 38 - Google hash

3.3.2.2 Base64 Debugging

The first stage of debugging was to pinpoint where the discrepancy was coming from. Out of the two possible hashes obtained, the correct hash had to be identified. Both hashes were searched in Shodan, as seen in **Figures 39 and 40**, where the results for each hash were examined.

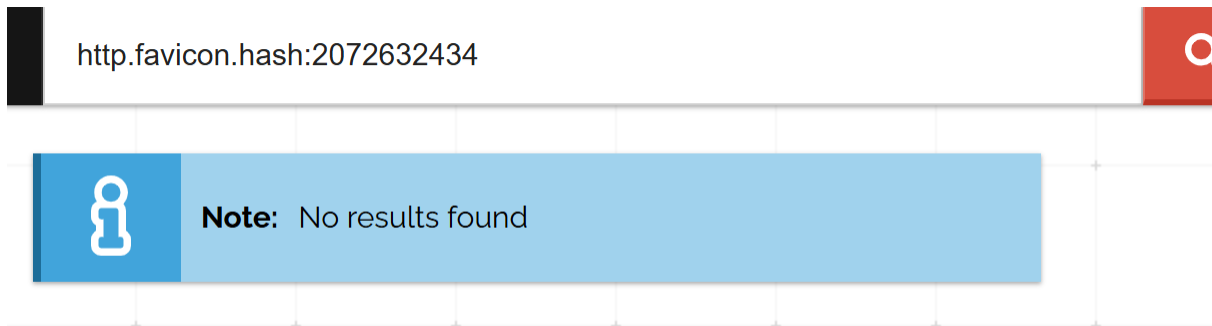

Figure 39 - Hash 2072632434

A screenshot of the Shodan search interface showing results for the hash 'http.favicon.hash:-1640178715'. The search bar at the top contains the hash. Below the search bar, there are navigation links: 'View Report', 'Download Results', 'Historical Trend', 'View on Map', and 'Advanced Search'. A banner for 'Access Granted' is visible. The results section shows a single result for 'reddit.com', including details about the SSL certificate and HTTP status.

IP Address	Domain	SSL Certificate	HTTP Status
151.101.193.140	reddit.com	Issued By: DigiCert Global G2 TLS RSA SHA256 2020 CA1 Issued To: *.reddit.com Organization: REDDIT, INC. Supported SSL Versions: TLSv1.2, TLSv1.3	HTTP/1.1 403 Blocked Connection: close Content-Length: 190240 Retry-After: 0 Content-Type: text/html Cache-Control: private, no-store Accept-Ranges: bytes Date: Sat, 26 Apr 2025 17:11:42 GMT Via: 1.1 varnish Strict-Transport-Security: max-age=31536000; includeSubdomains X-Content-Type-Options: ...

Figure 40 - Hash -1640178715

As shown in **Figure 39**, the hash “2072632434” – returned from the script when “reddit.com” was entered - did not return any results, while the hash “-1640178715” returned a result with the Reddit favicon. This

confirms that the hash value obtained from the script was incorrect, and the hash value from the generator was correct. As the file was being read in as raw binary data, it was theorised that the binary data was providing incorrect results. To rectify this, the data was encoded in base64 formatting, as base64 encodes data into a consistent ASCII format.

```
with open("favicon.ico", "rb") as file:
    b64_image = base64.b64encode(file.read())
    fav_hash = mmh3.hash(b64_image)
    #outputs the hash
    print(f"The favicon hash is: {fav_hash}")
    return fav_hash
```

Figure 41 - Base64 encoding

Once this was added, the function had to be tested again.

3.3.2.3 Get_address() Test Case 2

The second test case for this function is outlined in **Table 14**, with the results displayed in **Figures 42-45**.

Table 14: Test Case #007

Test Case ID	Objective	Input	Expected Output	Actual Output
#007	Confirm that the favicons are being hashed correctly	Reddit.com	-1640178715	1813988124
		Bbc.co.uk	111446429	-745405621
		Youtube.com	1179099333	1908550794
		Google.com	708578229	400996543

```
reddit.com
The favicon hash is: 1813988124
```

Figure 42 - Reddit hash

```
bbc.co.uk
The favicon hash is: -745405621
```

Figure 43 - BBC hash

```
youtube.com
The favicon hash is: 1908550794
```

Figure 44 - YouTube hash

```
google.com
The favicon hash is: 400996543
```

Figure 45 - Google hash

As displayed, the expected results once again did not match the actual results.

3.3.2.4 UTF8 Debugging

Following more research on base64 encoding, it was found that, though base64 encodes data into ASCII data, it is still being stored as bytes (freeCodeCamp, 2023). To convert the bytes to a string, the base64 data was decoded into a UTF-8 format, the most widely used form of encoding text (MDN, 2023). This is shown below in **Figure 46**.

```
with open("favicon.ico", "rb") as file:
    #encodes the file into base 64
    b64_image = base64.b64encode(file.read())
    #gets string representation of the file by decoding it to UTF-8
    utf8_b64 = b64_image.decode('utf-8')
    #formats the string into lines every 76 characters to comply with MIME standards
    line_split = re.sub("(.{76}|$)", "\\1\\n", utf8_b64, 0, re.DOTALL)
    #hashes the string representation of the favicon
    fav_hash = mmh3.hash(line_split)
    #outputs the hash
    print(f"The favicon hash is: {fav_hash}")
    return fav_hash
```

Figure 46 - UTF-8 encoding

Regex was employed to group 76 characters and split all groups of 76 characters onto separate lines, as this is the maximum line length allowed by MIME encoding standards with base64 data (IBM, 2025). Though the final format is UTF-8, the base64 encoding is kept. This is to ensure the data being encoded into UTF-8 is in a consistent format each time, rather than encoding raw binary bytes. Following this modification, the function had to be retested.

3.3.2.5 Get_hash() Test Case 3

Table 15 and **Figures 47-50** contain the test case for this iteration of the function.

Table 15: Test Case #008

Test Case ID	Objective	Input	Expected Output	Actual Output
#008	Confirm that the favicons are being hashed correctly	Reddit.com	-1640178715	-1640178715
		Bbc.co.uk	111446429	111446429
		Youtube.com	1179099333	1179099333
		Google.com	708578229	708578229

```
reddit.com
The favicon hash is: -1640178715
```

Figure 47 - Reddit hash

```
bbc.co.uk
The favicon hash is: 111446429
```

Figure 48 - BBC hash

youtube.com
The favicon hash is: 1179099333

Figure 49 - YouTube hash

google.com
The favicon hash is: 708578229

Figure 50 - Google hash

As displayed, the expected output now matched the actual output. To ensure these returned hashes were correct, they were all put into Shodan, as demonstrated in **Figures 51-54**.

Figure 52 - BBC hash in Shodan

As evidenced, the hashes returned from the script matched favicons when put into Shodan. After debugging the function, the expected results matched the actual results, marking this function as complete. The final iteration of the function can be viewed in **Figure 55**.

```

def get_hash(url):
    """
    This function hashes the favicon of the provided website.
    Returns:
    | mmh3 hash of the website's favicon
    """

    try:
        response = requests.get(url, timeout=10)
        #if the response code is 200 (the favicon was reached)
        if response.status_code == 200:
            #saves the favicon to a file
            with open("favicon.ico", 'wb') as file:
                file.write(response.content)

            #reads and hashes the file
            with open("favicon.ico", "rb") as file:
                #encodes the file into base 64
                b64_image = base64.b64encode(file.read())
                #gets string representation of the file by decoding it to UTF-8
                utf8_b64 = b64_image.decode('utf-8')
                #formats the string into lines every 76 characters to comply with MIME standards
                line_split = re.sub("(.{76})$", "\\1\\n", utf8_b64, 0, re.DOTALL)
                #hashes the string representation of the favicon
                fav_hash = mmh3.hash(line_split)
                #outputs the hash
                print(f"The favicon hash is: {fav_hash}")
                return fav_hash
            else:
                print("Failed to download favicon")
        except requests.exceptions.RequestException as e:
            print(f"Could not reach favicon: {e}")

```

Figure 55 - Get_hash() function

3.3.3 Processing URL Summary

To summarise, the processing URL module first verifies the network status of the target website and, if it can be reached, hashes the site's favicon into the correct format required for Shodan searches. This step was vital to the aim of accurately identifying phishing websites, as submitting an incorrectly formatted hash would lead to false or missing results. Through testing and debugging, the function was refined to consistently produce the correct favicon hashes, ensuring that phishing websites could be reliably detected. This also ensures that the objective of hashing the favicon was achieved. By achieving this objective, this module directly supports the wider project aim of detecting phishing websites based on the favicon. **Table 16** below contains a summary of functions in this module.

Table 16: Summary of processing URL functions

Function	Use
Reach_address()	Tests if the website can be reached. If not, the program exits early. If it can be reached, the favicon of the website is downloaded.
Get_hash()	Encodes the favicon into UTF-8 encoding and hashes the favicon in Murmur hash format.

3.4 SHODAN SEARCHING

After confirming that the favicon was being hashed correctly, the next step was to develop a method of searching for other websites using the same favicon. This was done by using Shodan. Shodan is a search

engine that contains details of devices connected to the internet, with an option to filter search results by the favicon. Using the Shodan API, this could be integrated into the Python script.

3.4.1 Shodan API

This module invokes the Shodan API to search Shodan and filter results to websites using the same favicon. To use the Shodan API, the user must create an account with Shodan and obtain their API key. It must be noted that, for this script's functionality, the Shodan account must be at least "member" level or registered with an academic email. For security reasons, the API is not embedded in the script. If the API key were to be in the script directly, anyone with the script would be able to use the API key. As API keys typically have limits, such as the number of uses they have, each user must have their API key. To ensure that the API key was not hardcoded in the script but still accessible, the API key was stored in an environment variable. Environment variables are configured outside of the program but can still be accessed by it during execution and are local to machines. Because they are local to machines, the API key is secure even if unauthorised users gain access to the script. To run the script, each user should obtain their own API key and create their environment variable. An example environment variable can be seen in **Figure 56**.

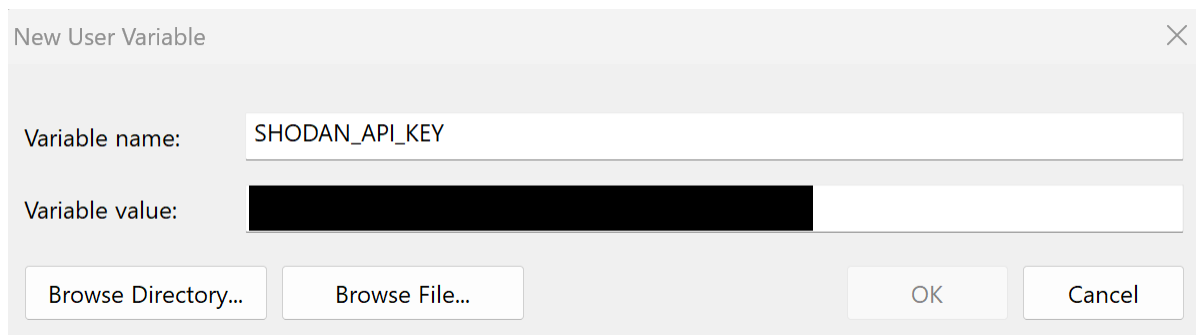

Figure 56 - Setting API key as an environment variable

3.4.2 Search()

The only function in this module – "search()" – takes the previously obtained favicon hash and invokes the Shodan API, passing in the favicon hash and searching Shodan with this hash. As displayed in **Figure 57**, the API key is fetched using the OS module and stored in a variable.

```
#gets the API key from the environment variable
shodan_api_key = os.getenv("SHODAN_API_KEY")
api = shodan.Shodan(shodan_api_key)
```

Figure 57 - Fetching the API key

The line:

`"api = shodan.Shodan(shodan_api_key)"`

Creates a Shodan object using the API key. This is what enables the script to use Shodan's services (achilleian, 2018). The Shodan object is then used to search Shodan and return all results in a dictionary, using the "search()" function from the Shodan object (achilleian, 2018). This is achieved through the following line of code:

```
"results = api.search(f"http.favicon.hash:{favicon_hash}")"
```

This line applies the necessary filter to search for favicon hashes and passes in the previously obtained favicon hash. To ensure robustness, the code first checks for the existence of the API key before attempting to use the API key. If the key is not found, the script returns the message "Shodan API key not found" and does not proceed further. This is demonstrated in **Figure 58**.

```
if shodan_api_key:
    try:
        #uses the Shodan search API to search for the hash
        results = api.search(f"http.favicon.hash:{favicon_hash}")
        return results
    except shodan.APIError as e:
        print(f"Error: {e}")
        return
else:
    print("Shodan API Key not found.")
    return
```

Figure 58 - Searching Shodan

3.4.2.1 Search() Test Case 1

To test the search() function, the *JSON* library was used to write the returned data to a file in a readable format. This can be seen in **Figure 59**.

```
results = api.search(f"http.favicon.hash:{favicon_hash}")
with open('results.json', 'w') as f:
    json.dump(results, f, indent=2)
```

Figure 59 - Outputting results to a file

The test case for this function is outlined below. Due to the varying nature of the data that could be returned, a more general expected output was opted for.

Table 17 - Test Case #009

Test Case ID	Objective	Input	Expected Output	Actual Output
#009	Verify that the API returns accurate data from Shodan	Reddit.com	Results match the results when Shodan is searched manually	Results match the results when Shodan is searched manually
		Google.com	Results match the results when Shodan is searched manually	Results match the results when Shodan is searched manually

		Youtube.com	Results match the results when Shodan is searched manually	Results match the results when Shodan is searched manually
		Bbc.co.uk	Results match the results when Shodan is searched manually	Results match the results when Shodan is searched manually

The results gained after searching Shodan for each hash manually are displayed below in **Figures 60-67**, with the results gained from running the script in **Figures 68-71**.

Figure 71 - Google script result

As evidenced, the search() function returns the same data categories that are returned when manually searching Shodan.

3.4.2.2 Search() Test Case 2

To further assess this module's success, an address from each output result was navigated to in a browser to verify the favicon. The following IP addresses were gained from running the script:

- Reddit - 151.101.129.140
- BBC - 212.58.244.68
- YouTube – 107.148.30.18
- Google - 142.250.31.99

The IP addresses found from the script output can be seen in **Figures 72-75**.

```

Figure 75 - Google favicon IP address

The test case is outlined in the table below, with supporting figures in **Figures 76-79**.

Table 18: Test Case #010

Test Case ID	Objective	Input	Expected Output	Actual Output
#010	Verify that the correct sites are being returned by checking the favicon	151.101.129.140	The Reddit favicon	The Reddit favicon
		212.58.244.68	The BBC favicon	The BBC favicon
		107.148.30.18	The YouTube favicon	The YouTube favicon
		142.250.31.99	The Google favicon	The Google favicon

Gallery on ReddPics | R
206.189.221.253

Figure 76 - 202.189.221.253 favicon

Figure 77 - 212.58.244.68 favicon

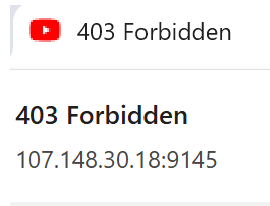

Figure 78 - 107.148.30.18 favicon

Figure 79 - 142.250.31.99 favicon

It should be noted that the IP address for Google automatically redirected the browser to google.com, hence why there is no IP address displayed in **Figure 77**.

3.4.2.3 Search() Test Case 3

After establishing that the program returns the expected results with a valid API key, it was necessary to test that the program exists gracefully if an invalid API key is returned. To test this, a false API key was hardcoded into the program, as seen in **Figure 80**, and then a blank API key was hardcoded as in **Figure 81**.

```
shodan_api_key = "asdf"  
api = shodan.Shodan(shodan_api_key)
```

Figure 80 – False API key

```
shodan_api_key = ""  
api = shodan.Shodan(shodan_api_key)
```

Figure 81 - Blank API key

The test case for this scenario is outlined below.

Table 19: Test Case #011

Test Case ID	Objective	Input	Expected Output	Actual Output
#011	Test error handling with invalid API keys	"asdf"	Shodan API error message	Shodan API error message
		Blank API key ("")	Shodan API key not found	Shodan API key not found

As displayed below in **Figures 82 and 83**, the program handles the errors as expected.

```
Error: Invalid API key  
PS C:\Users\laund\Documents\University\CMP320 - Advanced Ethical Hacking\Scripting Project>
```

Figure 82 - Invalid API key (asdf)

```
Shodan API Key not found.  
PS C:\Users\laund\Documents\University\CMP320 - Advanced Ethical Hacking\Scripting Project>
```

Figure 83 - Blank API key

As evidenced, the program handles invalid API keys correctly as expected and does not crash.

3.4.2.4 Search() Test Case 4

The final stage of testing the search() function involved testing an empty result from Shodan. It was vital to ensure that the program does not crash if no results are found from the Shodan search. To test this, a false favicon hash was hardcoded into the program, and the Shodan search modified to accept this false hash as seen in **Figure 84**.

```
false_hash = 239457861
if shodan_api_key:
    try:
        #uses the Shodan search API to search for the hash
        results = api.search(f"http.favicon.hash:{false_hash}")
        with open ("results.json", "w") as f:
            json.dump(results, f, indent = 2)
    return results
```

Figure 84 - False favicon hash

The test case for this is outlined in **Table 20**, with **Figure 85** containing the output.

Table 20: Test Case #012

Test Case ID	Objective	Input	Expected Output	Actual Output
#012	Test that the program can handle an empty result	False hash (239457861)	An empty file	{ "matches": [], "total": 0 }

```
{
  "matches": [],
  "total": 0
}
```

Figure 85 - Test Case #012 output

As demonstrated, the expected output of an empty file did not match the actual output. However, the program still returns a valid output, as the program does not crash, and there are no results displayed. Because the program returns a valid output, the lines:

"with open('results.json', 'w') as f:

json.dump(results, f, indent=2)"

Were removed as the full results no longer needed to be output every time the function ran. The full function can be viewed below in **Figure 86**.

```
def search(favicon_hash):
    """Search for favicon hash on Shodan using the Shodan API.
    Calls the search_results.process_results function, passing in the results and favicon hash.
    Arguments:
        favicon_hash: mmh3 hash of website favicon
    Returns:
        results | none: returns the results variable if successful, else returns nothing.
    """
    #gets the API key from the environment variable
    shodan_api_key = os.getenv("SHODAN_API_KEY")
    api = shodan.Shodan(shodan_api_key)

    if shodan_api_key:
        try:
            #uses the Shodan search API to search for the hash
            results = api.search(f"http.favicon.hash:{favicon_hash}")
            return results
        except shodan.APIError as e:
            print(f"Error: {e}")
            return
    else:
        print("Shodan API Key not found.")
        return
```

Figure 86 - Search() function

3.4.3 Shodan Searching Summary

In summary, this module interacts with the Shodan API to search for websites based on the target website's favicon hash. For security, the API key is stored in an environment variable and accessed through the OS library. Once retrieved, the key is used to query Shodan for the specified favicon hash. If a valid API key is detected, the program proceeds and returns the results in a dictionary format (achillea, 2018). If an invalid API key is fetched, the program displays an error message and stops without crashing. Similarly, if no results are returned, the program returns a file with no results and does not crash.

Testing showed that, with a valid API key, the module successfully retrieved search results matching that of the provided favicon hash, with the same data returned as a manual Shodan search. This stage was critical in gathering data required for identifying potential phishing websites, as it provided the raw data necessary for further filtering. Without the search results from Shodan, subsequent analysis would not have been possible. Completing this stage also fulfilled the objective of searching for a favicon on Shodan. By linking Shodan results to a favicon, this module directly contributes to the project's aim of detecting phishing websites, as it provides the functionality to search by favicon. **Table 21** outlines a summary of the functions utilised within this module.

Table 21: Shodan Searching functions

Function	Purpose
Search()	Fetches the API key and searches Shodan for the favicon hash. Any results are returned into a dictionary to be passed further into the program for filtering.

3.5 RESULTS FILTERING

After verifying that the Shodan searching module returned the correct information, a results filtering module had to be implemented. This module had to test each result returned from Shodan and filter out any legitimate results, leaving only results that were deemed suspicious. The criteria that the script used to filter results were:

- Unusual ports
- Suspicious domain characteristics
- No/self-signed SSL certificate

To store all suspicious sites, a global dictionary was used. A dictionary was used, rather than a list, as this structure allows storage of multiple attributes (such as IP address and port) for each result. A global variable was used to allow all functions easy access to the data. This dictionary was called “potential_phishing_sites”.

3.5.1 Port_test()

The first function developed in the results filtering stage was the port_test() function. This function searches through the results dictionary passed in from the Shodan searching module and searches for the port entry for each result. If a result used a port other than the standard 80 (HTTP) or 443 (HTTPS), the IP address for that result is added to the global dictionary. The function is seen below in **Figure 87**.

```
def port_test(results):
    """Tests for non-standard ports in use by the address.
    Arguments:
    | results (dict): The scan results from shodan
    Returns:
    | nothing"""
    for result in results['matches']:
        ip = result.get("ip_str")
        port = int(result.get('port'))
        if port not in [80, 443]:
            #creates an empty dict in the dict
            potential_phishing_sites[ip] = {}
            #adds the ip and port to the new dict
            potential_phishing_sites[ip][port] = {
                "Reason": "Non-standard port"
            }
```

Figure 87 - Port_test()

The function loops through the results dictionary searching for “matches”, as “matches” is the name of the dictionary key returned by Shodan. This is demonstrated in **Figure 85**. The function iterates through the results dictionary and searches for the ip_str and port attributes to get the IP address and port of the current result. If the port used was not 80 or 443, the IP address and port used were added to the

dictionary. Specifically, these were added to a new dictionary in the dictionary, creating a dictionary of dictionaries. This allowed each IP address to store multiple ports, in case multiple ports were open on one IP address. Each nested dictionary also contains a reason for suspicion – in this case, it was a non-standard port.

3.5.1.1 Port_test() Test Case 1

To test this function, the favicon hash was input, the dictionary was printed, and the results were examined. The hash used in this case was -1640178715, the favicon hash of Reddit.

Table 22: Test Case #013

Test Case ID	Objective	Input	Expected Output	Actual Output
#013	Verify that the port_test() function returns a list of results that use unusual ports	-1640178715	Two IP addresses: 64.226.69.42 and 47.57.0.169	Two IP addresses: 64.226.69.42 and 47.57.0.169

As stated in Table 22 and displayed below in Figure 88, the script returned both IP addresses.

```
{'47.57.0.169': {'8096': {'Reason': 'Non-standard port'}}, '64.226.69.42': {'81': {'Reason': 'Non-standard port'}}}
```

Figure 88 - Two IP addresses

As evidenced, the results from the script matched up with the two IP addresses from a manual Shodan search.

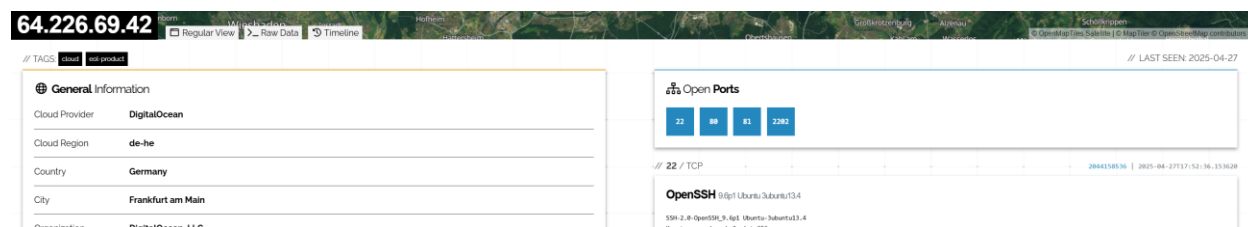

Figure 89 - 64.226.69.42 ports

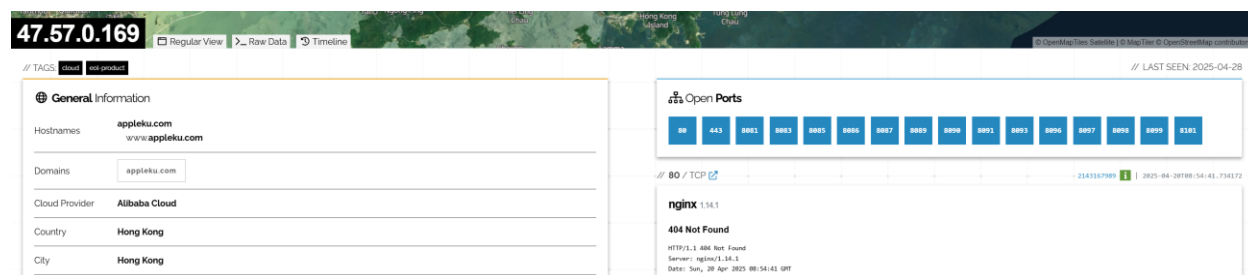

Figure 90 - 47.57.0.169 ports

3.5.2 Add_reason()

Before moving on to the next test, a function called “add_reason()” was added to streamline the process of collecting potentially suspicious addresses. This function centralises the logic required to update the

potential phishing sites dictionary. Without a function, the block of code pictured in **Figure 91** would need to be repeated whenever a new test is performed. By adding a function, this removes the need for repetitive blocks of code, improving efficiency and readability.

```
#creates an empty dict in the dict
potential_phishing_sites[ip] = {}
#adds the ip and port to the new dict
potential_phishing_sites[ip][port] = {
    "Reason": "Non-standard port"
}
```

Figure 91 - Repeated code

The function takes an IP address, port, reason for suspicion, and the full result from Shodan. Passing the result into the function ensured it could be stored to allow inspection of all details of the result. The function can be seen below in **Figure 92**.

```
def add_reason(ip, port, result, reason):
    """Adds reason for a specific IP-port combination.
    Arguments:
        ip: the address of the website
        port: the port of the web address being tested
        result: an item in the results dict
        reason: reason for suspicion
    Returns:
        nothing
    """
    #creates an entry in the dict if the IP is not found
    if ip not in potential_phishing_sites:
        potential_phishing_sites[ip] = {}
    #if the IP is found but the port is not, adds it to the dict along with the reasons
    if port not in potential_phishing_sites[ip]:
        potential_phishing_sites[ip][port] = {
            "reasons": [reason],
            "details": result
        }
    #if the reason has not already been added, add it
    elif reason not in potential_phishing_sites[ip][port]["reasons"]:
        potential_phishing_sites[ip][port]["reasons"].append(reason)
```

Figure 92 - Add_reason()

To ensure robustness, the function includes the following checks:

- A check to see if the IP address exists in the dictionary
- A check to see if the current port exists under the current IP address
- A check to see if the current reason for suspicion exists in the dictionary

The program must check to see if the IP address exists in the dictionary because, if it does not exist and the program tries to add it, it may behave unexpectedly. The program adds an empty entry for the

current IP address so that information can be added if required. Then, the program checks to see if the current port exists under the current IP address in the dictionary. This allows for multiple ports to be linked to the same IP address and ensures that the data in the dictionary does not get overwritten. If the port is not found, it will add the reason for suspicion to the dictionary and store the entire result returned from Shodan for the current address in the dictionary as well. This allows all details for the current address to be fetched. Unlike the previous block of code (**Figure 91**), “reasons” becomes a list in the dictionary, enabling multiple reasons for suspicion to be stored with the same IP and port combination. The program finally checks to see if the current IP and port combination matches the current reason in the dictionary. This allows the IP and port combination to have multiple reasons and ensures it will not get written over.

3.5.2.1 Add_reason() Test Case

To test the add_reason() function, the function was called with sample data and tested using the “assert” statement. The assert statement is used to test conditions to aid debugging. If the condition is true, nothing returns. If the condition is false, the program will return an error. As shown in **Figure 93**, the assert statement is used to test if the IP addresses have been added to the dictionary. As well as sample data, the shodan_search() module was invoked to pass the result of a Shodan search into the function, to verify that the full result is also being added to the dictionary. The dictionary is then printed to examine and confirm the contents. Some false data was also added to the assert statement to ensure thoroughness.

```
add_reason("192.168.0.1", 81, result, "Non-standard port")
add_reason("192.168.0.1", 82, result, "Non-standard port")
add_reason("192.168.0.1", 83, result, "Non-standard port")
add_reason("192.168.0.1", 84, result, "Non-standard port")
add_reason("192.168.0.2", 85, result, "Non-standard port")
add_reason("192.168.0.2", 86, result, "Non-standard port")
add_reason("192.168.0.2", 87, result, "Non-standard port")
add_reason("192.168.0.2", 88, result, "Non-standard port")
assert "192.168.0.1" in potential_phishing_sites, "IP not found"
assert 81 in potential_phishing_sites["192.168.0.1"], "Port 81 not found"
assert 82 in potential_phishing_sites["192.168.0.1"], "Port 82 not found"
assert 83 in potential_phishing_sites["192.168.0.1"], "Port 83 not found"
assert 84 in potential_phishing_sites["192.168.0.1"], "Port 84 not found"
assert "192.168.0.2" in potential_phishing_sites, "IP not found"
assert 85 in potential_phishing_sites["192.168.0.2"], "Port 85 not found"
assert 86 in potential_phishing_sites["192.168.0.2"], "Port 86 not found"
assert 87 in potential_phishing_sites["192.168.0.2"], "Port 87 not found"
assert 88 in potential_phishing_sites["192.168.0.2"], "Port 88 not found"
for port in [81, 82, 83, 84]:
    reasons = potential_phishing_sites["192.168.0.1"][port]["reasons"]
    assert "Non-standard port" in reasons, f"Reason not found for port {port}"
for port in [85, 86, 87, 88]:
    reasons = potential_phishing_sites["192.168.0.2"][port]["reasons"]
    assert "standard port" in reasons, f"Reason not found for port {port}"
```

Figure 93 - Testing add_reason()

The test case for this scenario is outlined below.

Table 23: Test Case #014

Test Case ID	Objective	Input	Expected Output	Actual Output
#014	Verify the add_reason() function operates correctly	“Assert “192.187.120.2””	“192.187.120.2 not found”	“192.187.120.2 not found”
		See assert statements in Figure 93	No output (the assert statements return true)	No output (the assert statements return true)
		“assert "standard port" in reasons, f"Reason not found for port {port}””	“Reason not found for port <port>”	“f”Reason not found for port {port}””
		“print(potential_phishing_sites)”	A dictionary full of Shodan result information	A dictionary full of Shodan result information

For more details on the output gained, see **Figures 94-96**.

    ^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^
```

Figure 95 - Port not found

ends with any of these domains. If it does, the result is added to the potential phishing sites dictionary (**Figure 97**).

To test for short domain names, the script splits up domains using the full stop (".") symbol and checks the length of the portion before the split. If this portion is less than four characters long, this result gets added to the dictionary (**Figure 98**).

When testing for excessive hyphens, the *count* predefined function is used to check for more than two hyphens. If more than two hyphens are found, the address gets added to the dictionary (**Figure 99**).

To test for several subdomains, the *count* function is invoked again to test for more than three full stops and adds the result to the dictionary if more than three are found (**Figure 100**).

Finally, regex is used to search for suspicious keywords in the domain (such as login, bank, account, etc), adding the result to the dictionary if any are found (**Figure 101**).

```
for result in results['matches']:
    hostnames = result.get("hostnames", [])
    ip = result.get("ip_str")
    for hostname in hostnames:
        for domain in domains:
            #checks for suspicious TLD
            if hostname.endswith(domain):
                add_reason(ip, result.get('port'), result, "Domain TLD is suspicious")
                break
```

Figure 97 - Testing TLD

```
break
#checks for a short domain name
domain_part = hostname.split(".")[-2] if "." in hostname else hostname
if len(domain_part) < 4:
    add_reason(ip, result.get("port"), result, "Domain name is very short")
```

#checks for suspicious keywords
if re.search(r"(login|verify|update|secure|account|bank|paypal)", hostname):
    add_reason(ip, result.get("port"), result, "Domain name " \
        "contains suspicious keywords")
```

Figure 101 - Testing for keywords

3.5.3.1 Domain_test() Test Case

To test this function, Shodan was manually searched with the favicon hash “-1640178715” – the hash for Reddit. The objective of this was to note any results that matched the suspicious domain criteria for the script and compare this to the output of the script. As shown in **Figure 102**, only one result contained a domain that would match the criteria of the script.

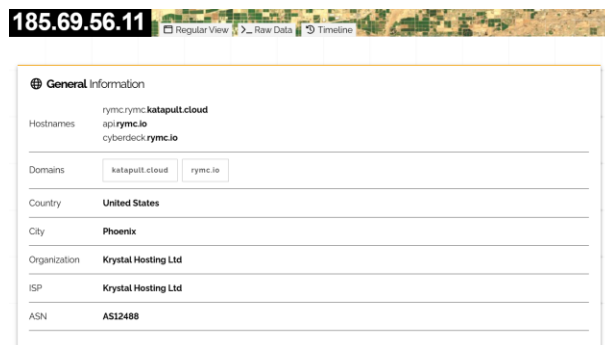

Figure 102 - Suspicious domain

To test if this was added to the dictionary, the Shodan search module was again invoked, and reddit.com was input. The results from this search were then passed into the domain_test() function. The assert statement was used to verify that the above address, 185.69.56.11, and no other addresses, were added to the dictionary. This can be seen below, in **Figure 103**.

```
assert "185.69.56.11" in potential_phishing_sites, "IP not found"
assert "207.246.76.189" not in potential_phishing_sites, "IP should not be found"
assert "47.57.0.169" not in potential_phishing_sites, "IP should not be found"
assert "206.189.221.253" not in potential_phishing_sites, "IP should not be found"
assert "185.219.132.188" not in potential_phishing_sites, "IP should not be found"
assert "182.92.183.18" not in potential_phishing_sites, "IP should not be found"
assert "64.226.69.42" not in potential_phishing_sites, "IP should not be found"
assert "206.189.221.253" not in potential_phishing_sites, "IP should not be found"
assert "185.92.183.18" not in potential_phishing_sites, "IP should not be found"
assert "185.219.132.188" not in potential_phishing_sites, "IP should not be found"
assert "64.226.69.42" not in potential_phishing_sites, "IP should not be found"
assert "185.92.183.18" not in potential_phishing_sites, "IP should not be found"
assert "185.219.132.188" not in potential_phishing_sites, "IP should not be found"
```

Figure 103 - Testing domain_test()

Although this tested the TLD check, it did not sufficiently test any other checks. To test all the checks, a list of sample data was created and used in the `domain_test()` function. The list of data can be seen below in **Figure 104**.

```
sample_results = {
  "matches": [
    {
      "ip_str": "192.168.0.10",
      "port": 8080,
      "hostnames": ["login-bank.tk"]
    },
    {
      "ip_str": "192.168.0.11",
      "port": 443,
      "hostnames": ["a-b-c-d.example.net"]
    },
    {
      "ip_str": "192.168.0.12",
      "port": 80,
      "hostnames": ["x.io"]
    },
    {
      "ip_str": "192.168.0.13",
      "port": 8443,
      "hostnames": ["update.secure.verify.example.co.uk"]
    }
  ]
}
```

Figure 104 - Sample data

This sample mimics the data structure returned from Shodan. The assert statement was then used on the above IP addresses. This can be seen below in **Figure 105**.

```

#192.168.0.10 tests

```

Figure 105 - Testing domains

The test case for this function is outlined in **Table 24**.

Table 24: Test case #015

Test Case ID	Objective	Input	Expected Output	Actual Output
#015	Test the domain_test() function	Sample data displayed in Figure 105	No output (the assert statements return true)	No output

As can be seen in **Figure 106**, there was no output from the program. This meant that the assert statements all returned true, meaning that the domain_test() function is working correctly.

```

PS C:\Users\laund\Documents\University\CMP320 - Advanced Ethical Hacking\Scripting Project> python .\phavicon_phisher.py
PS C:\Users\laund\Documents\University\CMP320 - Advanced Ethical Hacking\Scripting Project> 

```

Figure 106 - No output from domain_test()

3.5.4 SSL_test()

The final testing function to be developed was the Secure Socket Layer (SSL) test. This function tests for any addresses that have either a self-signed SSL certificate or no SSL certificate at all. Self-signed certificates are SSL certificates that are created and authenticated by the organisation that is going to use them (Tucker, 2024). Unlike a Certificate Authority (CA) signed SSL certificates, self-signed certificates are not verified by any other organisation. Additionally, if a website doesn't have an SSL certificate at all, there is no encryption in use on the site. To develop this function, the "SSL" attribute was retrieved from the Shodan result and, if it was not empty, was split into "issuer" and "subject". These were compared,

and if they were the same, the IP and port combination was added to the dictionary with the reason “Self-signed SSL certificate”. If the SSL attribute was empty, the script added the IP and port combination to the dictionary with the reason “No SSL certificate”, and the details were saved to the current result dictionary. If the SSL attribute was not empty and not self-signed, the subject and issuer were added to the current result. The function can be seen in **Figure 107**.

```
def ssl_test(results):
    """Tests for self-certified SSL certs or lack of SSL cert.
    Arguments:
        results (dict): The scan results from shodan
    Returns:
        nothing."""

    for result in results['matches']:
        ip = result.get("ip_str")
        ssl_cert = result.get('ssl', {})
        port = int(result.get('port'))
        #if no SSL certificate is found
        if not ssl_cert:
            add_reason(ip, port, result, "No SSL certificate")
        #if the SSL cert is not empty
        elif ssl_cert != "" and ssl_cert != {}:
            #assigns variables to data from the result
            cert = ssl_cert.get('cert', {})
            issuer = cert.get('issuer', {})
            subject = cert.get('subject', {})
            #tests for self signed certificate
            if issuer == subject and issuer != {} and issuer != "":
                add_reason(ip, port, result, "Self-signed SSL certificate")
                result["ssl_subject"] = subject
                result["ssl_issuer"] = issuer
```

Figure 107 - Ssl_test()

3.5.4.1 SSL_test() Test Case

To test this function, another sample dictionary was created that matched the structure of the result returned from Shodan. This can be seen in **Figure 108**.

```

sample_results = {
  "matches": [
    #no SSL certificate
    {
      "ip_str": "192.0.2.1",
      "port": 443,
      "ssl": {}
    },
    #self-signed certificate
    {
      "ip_str": "192.0.2.2",
      "port": 443,
      "ssl": {
        "cert": {
          "issuer": {
            "CN": "Self-signed"
          },
          "subject": {
            "CN": "Self-signed"
          }
        }
      }
    },
    #third party signed certificate
    {
      "ip_str": "192.0.2.3",
      "port": 443,
      "ssl": {
        "cert": {
          "issuer": {
            "CN": "CA cert"
          },
          "subject": {
            "CN": "example.com"
          }
        }
      }
    }
  ]
}

```

Figure 108 - SSL_test() sample data

Again, assert statements were used to test the expected output. These can be seen in **Figure 109**.

```

assert "192.0.2.1" in potential_phishing_sites, "192.0.2.1 not found"
assert "192.0.2.2" in potential_phishing_sites, "192.0.2.2 not found"
assert "192.0.2.3" not in potential_phishing_sites, "192.0.2.3 is found"

```

Figure 109 - SSL_test() asserts

The table below contains the test case used to test this function.

Table 25: Test Case #016

Test Case ID	Objective	Input	Expected Output	Actual Output
#016	Verify the ssl_test() function operates correctly	Sample data displayed in Figure 109	No output (the assert statement returned true)	No output

As stated by **Table 25**, and displayed in **Figure 110**, the program returned no output. This confirmed that the program was functioning as expected.

```
PS C:\Users\laund\Documents\University\CMP320 - Advanced Ethical Hacking\Scripting Project> python .\phavicon_phisher.py
PS C:\Users\laund\Documents\University\CMP320 - Advanced Ethical Hacking\Scripting Project> █
```

Figure 110 - No output

3.5.5 Process_results()

The final function to be developed with the “process_results()” function. This function links all the functions previously described in this module together and outputs the results to the user. The function calls the previously described test functions and loops through the potential phishing sites dictionary, adding it to a new dictionary called “ip_port_reason”. This dictionary was used to organise the data obtained from the potential phishing sites dictionary. This makes it easier to output the data, as it means the potential phishing sites' data does not need to be directly processed. Instead, the data is converted into a structured format and then output. The data structure used for ip_port_reason is a “default dict”. This structure provides automatic presence checks, eliminating the need to do these manually. (GeeksforGeeks, 2025). This can be seen in **Figure 111**.

```
#empty dict for ip and port combinations
if not results or 'matches' not in results:
    print("No valid results returned from Shodan")
    return
ip_port_reasons = defaultdict(lambda: {
    "reasons": set(),
    "hostnames": [],
    "details": {}
})

port_test(results)
domain_test(results)
ssl_test(results)

for ip, port_data in potential_phishing_sites.items():
    for port, data in port_data.items():
        ip_port_key = (ip, port)

        #automatically adds the reasons to the set and hostnames to the list
        ip_port_reasons[ip_port_key]["reasons"].update(data["reasons"])
        ip_port_reasons[ip_port_key]["hostnames"].extend(h.lower() for h in data["details"].get('hostnames', []))
        ip_port_reasons[ip_port_key]["details"] = data["details"]
```

Figure 111 - Storing data in ip_port_reasons

After the results were stored in the new dictionary, this dictionary was traversed, with the contents being output to a file. This is demonstrated in **Figure 112**.

```

#outputs results to the text file
with open("FaviconPhisherOutput.txt", "w", encoding="utf-8") as f:
    f.write(f"Results found for hash {favicon_hash}:\n")
    f.write("-" * 40 + "\n")

    #loops through all the unique ip and port combinations
    for (ip, port), data in ip_port_reasons.items():
        f.write(f"IP: {ip}\n")
        f.write(f"Port: {port}\n")
        f.write(f"Hostnames: {' '.join(data['hostnames']) if data['hostnames'] else 'N/A'}\n")
        f.write(f"Location: {data['details'].get('location', 'N/A')}\n")
        f.write(f"Reasons: {' '.join(data['reasons'])}\n")
        f.write("-" * 40 + "\n")

```

Figure 112 - Writing to a file

After writing to a file, the URL entered by the user is split into IP/hostname and port, and that combination is checked against all IP/hostname and port combinations found in the list of suspicious sites. If the address is found in the list, the script outputs a warning message. This can be viewed in **Figure 113**.

```

#splits the ip and port
parsed = urlparse(address)
stripped_ip = parsed.hostname
stripped_port = parsed.port if parsed.port else (443 if parsed.scheme == "https" else 80)

#searches for the ip and port in the results and print a warning if matched
match_found = False
for (ip, port), data in ip_port_reasons.items():
    if ip == stripped_ip and port == stripped_port:
        match_found = True
        print("\n" + "=" * 60)
        print("WARNING: Potential Phishing Site Detected")
        print("=" * 60)
        print(f"Target IP      : {ip}")
        print(f"Target Port    : {port}")
        print("Reasons:")
        for reason in sorted(data['reasons']):
            print(f"  - {reason}")
        print("=" * 60 + "\n")
        break

print("\n" + "-" * 60)
print("Scan Complete")
print("-" * 60)
print("A list of other suspicious sites using this favicon has been \n" \
      "saved to: FaviconPhisherOutput.txt")
if not match_found:
    print("No flags were raised for the provided address.")
else:
    print("The provided address has been flagged. Review details above.")
print("Thank you for using FaviconPhisher.")
print("-" * 60 + "\n")
return

```

Figure 113 - Searching for a matched address

3.5.5.1 *Process_results()* Test Case

To test the `process_results()` function, the rest of the program was invoked to provide real test data, using “reddit.com”. This was effectively an “end-to-end” test of the program. The results gained from the

Shodan API were dumped into a JSON file, and each web address that matches one or more of the suspicion criteria was collected and can be viewed in **Appendix B – Shodan Raw Data**. Due to the extremely large output returned by Shodan, only the relevant addresses are included. These addresses are as follows:

- 47.57.0.169
- 185.69.51.11
- 185.219.132.188
- 64.226.69.42
- 185.92.183.18
- 207.246.76.189
- 206.189.221.253

There were two test cases carried out – one to test the writing to file, and one to test the command line output. These test cases are outlined below.

Table 26: Test Case #017

Test Case ID	Objective	Input	Expected Output	Actual Output
#017	Ensure the results are being written to a file correctly	Reddit.com	47.57.0.169 – Non-standard port, No SSL certificate	47.57.0.169 – Non-standard port, No SSL certificate
			185.69.51.11 – Domain TLD is suspicious	185.69.51.11 – Domain TLD is suspicious
			185.219.132.188 – Self-Signed SSL certificate	185.219.132.188 – Self-Signed SSL certificate
			64.226.69.42 – No SSL certificate, Non-standard port	64.226.69.42 – No SSL certificate, Non-standard port
			185.92.132.18 – Self-signed SSL certificate	185.92.132.188 – Self-signed SSL certificate
			207.246.76.189 – Domain has too many subdomains	207.246.76.189 – Domain has too many subdomains
			206.189.221.253 – No SSL certificate	206.189.221.253 – No SSL certificate

The results of the test can be viewed in **Figures 114 and 115**.

Reasons: Self-signed SSL certificate

Figure 115 - Results from Reddit.com

As demonstrated, the function wrote to the file correctly. The next test case was to test the command line output. If a site is found to be suspicious, the block of code in **Figure 113** should print a warning. If not, the code should print a message stating that the entered website is safe. To test this, a known safe site (reddit.com) and all the known suspicious sites returned from Shodan that match the Reddit hash were entered.

Table 27: Test Case #017

Test Case ID	Objective	Input	Expected Output	Actual Output
#017	Test the command line output	Reddit.com	Safe statement	Safe statement
		47.57.0.169:8096	Warning statement with reasons for non-standard port and no SSL certificate	Warning statement with reasons for the non-standard port and no SSL certificate

		64.226.69.42:81	Warning statement with reasons for non-standard port and no SSL certificate	Website could not be reached. Ensure you have a valid network connection
		185.69.56.11:443	A warning statement with the reason for the suspicious TLD	Website could not be reached. Ensure you have a valid network connection.
		207.246.76.189:443	A warning statement with the reason for too many subdomains	Address could not be reached. Website could not be reached. Ensure you have a valid network connection
		185.92.183.18:80	A warning statement with the reason for no SSL certificate	A warning statement with the reason for no SSL certificate
		185.92.183.18:443	A warning statement with the reason for the self-signed SSL certificate	Address could not be reached. Website could not be reached. Ensure you have a valid network connection
		185.219.132.188:443	A warning statement with the reason for the self-signed SSL certificate	Address could not be reached. Website could not be reached. Ensure you have a valid network connection.

As stated above, the safe site and two IP addresses returned the expected output, displayed in **Figures 116-117**.

Figure 118 - Results from 185.92.183.18

However, the rest of the addresses were unable to be reached. To verify this, each address was navigated to using a browser and it was confirmed that the addresses could not be reached. As the program was designed to proceed only if the response status code was 200, this meant that the program was functioning correctly, concluding the development of the processing URL stage.

3.5.6 Results Filtering Summary

To summarise, the results filtering module collects, tests, and filters addresses that use the same favicon as the website the user initially entered, before writing all suspicious sites to a file and finally outputting whether the user's entered address is suspicious. The module tests any addresses returned from Shodan for non-standard ports (ports other than 80 or 443), a self-signed SSL certificate or lack thereof, and tests for five different domain characteristics: suspicious TLD, very short domain name, excessive hyphens, too many subdomains, and suspicious keywords. Any address that flags up as suspicious from any of these tests is collected, with all suspicious sites being written out to a file. The module then searches the list of suspicious sites for the address the user entered and, if found, outputs a warning to the user that the address entered may belong to a phishing site. Through this functionality, this module directly contributes to the overall aim of detecting phishing sites based on the favicon, specifically fulfilling the objectives of comparing Shodan results to specific criteria and stating whether the given address is likely a phishing site.

Table 28 below contains a summary of functions used in this module.

Table 28: Functions used in the processing results stage

Function	Purpose
Add_reason()	Adds suspicious results to a dictionary along with the relevant port and reason for suspicion
Port_test()	Tests all results returned from Shodan for a port other than 80 or 443
Domain_test()	Tests all results returned from Shodan for: a suspicious TLD, short domain name, many subdomains, many hyphens, suspicious keywords
Ssl_test()	Tests all results returned from Shodan for a self-signed or no SSL certificate
Process_results()	Calls all test functions, writes the result to a file, and outputs a message stating whether the user's entered address is suspicious.

3.6 CLEANING UP

To improve readability, each section was split into different files. Each file, which can be viewed in **Appendix A – PhaviconPhisher Code**, contains code about each stage of the methodology, the list of which is as follows:

- "user_input.py"
- "process_url.py"
- "shodan_search.py"
- "search_results.py"

- “phavicon_phisher.py”

The file “phavicon_phisher.py” is the file that links everything together, it contains all function calls required for the program’s operation and displays the name and author of the program.

To display the name, an ASCII representation of the script name was created using an ASCII text generator (patorjk, n.d). The *colorama* library was then used to style the ASCII art and change the text colour to green. This can be seen in **Figure 119**.

[illegible]

Figure 119 - ASCII art

Following the ASCII art, the *argparse* library was used to add a help option to the script. If a user uses the “-h” argument when running the script from the command line, a description of how to use the script is displayed. The code for this is displayed in **Figure 120**, and an example of this can be seen in **Figure 121**.

```
def arg_parse():
    """Parse command-line arguments.

    This function uses the argparse module to parse arguments.

    Returns:
        argparse.Namespace: The parsed arguments
    """

    #argparse use
    arg_parser = argparse.ArgumentParser(
        description="Favicon Phisher - A tool used to detect phishing sites using the favicon.",
        epilog="Usage: Enter an IPv4 address or website url, optionally specifying the port.\n" \
        "The script will return whether or not the website is likely a phishing site. \n" \
        "Developed by Jack Laundon. \n" \
        "Github: https://github.com/JackLaundon1",
        #formats the text
        formatter_class=argparse.RawTextHelpFormatter
    )

    return arg_parser.parse_args()
```

Figure 120 - Argparse code

```

PS C:\Users\laund\Documents\University\CMP320 - Advanced Ethical Hacking\Scripting Project> python .\phavicon_phisher.py -h
usage: phavicon_phisher.py [-h]

Favicon Phisher - A tool used to detect phishing sites using the favicon.

options:
  -h, --help  show this help message and exit

Usage: Enter an IPv4 address or website url, optionally specifying the port.
The script will return whether or not the website is likely a phishing site.
Developed by Jack Laundon.
Github: https://github.com/JackLaundon1

```

Figure 121 - Argparse help option

Finally, all the function calls were added to link everything together, as shown in **Figure 122**.

```

def main():
    """
    Entry point of the script.
    Calls arg_parse() to parse command line arguments.
    Then calls display() to show the ASCII art, followed by
    calling user_input.get_address() to get the web address from the user.
    Then, calls process_url.get_hash(), shodan_search.search(), search_results.process_results().
    Returns:
    | nothing
    """
    try:
        # Parse the command-line arguments
        arg_parse()
        #displays the graphic and start the address retrieval process
        display()
        #calls the user_input.get_address function to handle user input
        address = user_input.get_address()
        if not process_url.reach_address(address):
            print("Website could not be reached. Ensure you have a valid network connection")
            return
        #gets the hash of the file
        if address is None:
            print("Error: Unable to retrieve a valid address or favicon URL.")
            return
        #gets the hash of the favicon
        fav_hash = process_url.get_hash(address)
        #passes the hash into the shodan_search.search function
        results = shodan_search.search(fav_hash)
        #calls the process_results function
        search_results.process_results(results, fav_hash, address)
    #stops the program if the user interrupts
    except KeyboardInterrupt:
        print("\nInterrupted - script cancelled.")

```

Figure 122 - Function calls

After linking everything together, an end-to-end test was required. The test case is outlined below. Reddit.com was again entered to test the output for a known safe site, and “47.57.0.169:8096” was again used as a known suspicious site.

Table 29: Test Case #017

Test Case ID	Objective	Input	Expected Output	Actual Output
--------------	-----------	-------	-----------------	---------------

#017	Ensure the program operates correctly from start to finish	Reddit.com	ASCII art displaying the name of the program, the author's details, a file with suspicious sites and a message stating the site is safe	ASCII art displaying the name of the program, the author's details, a file with suspicious sites and a message stating the site is safe
		47.57.0.169:8096	ASCII art displayed the name of the program, the author's details, a file with suspicious sites and a message stating the site is unsafe for the reasons of no SSL certificate and a non-standard port	ASCII art displayed the name of the program, the author's details, a file with suspicious sites and a message stating the site is unsafe for the reasons of no SSL certificate and a non-standard port

As demonstrated below, in **Figures 123 and 124**, the expected output was returned from both inputs, concluding that the program functions correctly from start to end.

Figure 124 - 47.57.0.169:8096 output

3.6.1 Cleaning Up Summary

To summarise, the cleaning up portion of the development focused on splitting up the code into logical files to improve readability. This stage of development also included the addition of ASCII art to display the program name, and the help option presented via argparse.

3.7 DOCKER

The final stage of development was to integrate the script with Docker. This would ensure that the script could be run on any system or machine without relying on the installation of external dependencies. To do this, a Docker file was created to build the Docker container. The file, displayed in **Figure 125**, installs all dependencies required and then runs the program. The dependencies were stored in another file, “requirements.txt”, which can be viewed in **Figure 126**.

```

#python version
FROM python:3.9-slim

#sets the working directory
WORKDIR /app

#copies all files into the container
COPY . /app

#installs the dependencies contained in the requirements .txt file without caching them
RUN pip install --no-cache-dir -r requirements.txt

#runs the script
CMD ["python", "phavicon_phisher.py"]

```

Figure 125 - Docker file

```

shodan
colorama
requests
mmh3

```

Figure 126 - requirements.txt

The Docker container was built using the command:

"docker build -t phavicon_phisher .".

This can be seen in **Figure 127**.

```

```

Figure 127 - Building a Docker container

After the container was built, it was run using the command:

"docker run -e SHODAN_API_KEY <API key> -it --name phavicon_phisher_container phavicon_phisher".

The "-e" flag signifies the environment variable, in this case the API key, and the "-it" flag specifies that the container should be run in interactive mode. This allows the container to take user input, a fundamental component of the script.

3.7.1 Docker Test Case

With the container running, one final end-to-end test was required. Once again, reddit.com was used as a known safe site with "47.57.0.0.169:8096" as a known suspicious site.

Table 30: Test Case #018

Test Case ID	Objective	Input	Expected Output	Actual Output
#018	Ensure the program operates correctly from start to finish using Docker	Reddit.com	ASCII art displaying the name of the program, the author's details, a file with suspicious sites and a message stating the site is safe	ASCII art displaying the name of the program, the author's details, a file with suspicious sites and a message stating the site is safe
		47.57.0.169:8096	ASCII art displayed the name of the program, the author's details, a file with suspicious sites and a message stating the site is unsafe for the reasons of no SSL certificate and a non-standard port	ASCII art displayed the name of the program, the author's details, a file with suspicious sites and a message stating the site is unsafe for the reasons of no SSL certificate and a non-standard port

As demonstrated in **Figures 128 and 129**, the script functions correctly when run through Docker. This concluded the development of PhaviconPhisher.

3.7.2 Docker Summary

In summary, the Docker container packages all necessary files and dependencies to ensure that the script can be run on any machine or system. This completes the objective of ensuring that the script can run on any machine, which in turn supports the overarching goal of detecting phishing sites based on the favicon by ensuring that the script can function on any system.

3.8 SUMMARY OF RESULTS

Each stage described in the previous sections has its own results. Each set of results is imperative to the program as a whole – if one set of results were not gained, the script would not function.

3.8.1 User Input Results

As part of the greater aim of detecting phishing websites based on their favicon, the user input section set out to take input from the user and sanitise and validate the input. As outlined in **Section 3.1 – User Input**, the module sanitises the given address by removing any trailing or leading whitespace and trailing slashes. The module then validates the address by using regex to match the address against an expected format for IP or website addresses and then ensures that there is a valid HTTP(S) scheme prefixing the address. This provides the necessary input validation to ensure that the address is in the correct format to be used in the rest of the script – an incorrect format may provide unexpected results.

3.8.2 Processing URL Results

To support the goal of detecting phishing websites using the favicon, the processing URL stage attempts to reach the target website and, if successful, hashes the favicon in MurmurHash format. As described in **Section 3.2 – Processing URL**, the favicons were correctly hashed and verified. This ensured that the correct hash value was being passed into the Shodan API, therefore ensuring that the correct hash was being searched on Shodan.

3.8.3 Shodan Searching Results

Within the wider scope of identifying phishing websites based on their favicons, the Shodan searching module focused on using the Shodan API to search Shodan using a favicon. As stated in **Section 3.4 – Shodan Searching**, the Shodan API returned the expected data from Shodan. This provided the information required to filter out legitimate websites and leave only suspicious websites.

3.8.4 Processing Results

Contributing to the overall target of detecting phishing websites using the favicon, the processing results module performed three main tests on the results returned from the Shodan API:

- Testing for non-standard port
- Testing for self-signed/no SSL certificate
- Testing for suspicious domain characteristics
 - Many subdomains
 - Excessive hyphens
 - Suspicious keywords
 - Very short domains
 - Suspicious TLDs

As **Section 3.5 – Processing Results** describes, the information returned from Shodan was correctly filtered to output only suspicious websites. Therefore, any potential phishing websites are clearly communicated to the user.

3.8.5 End-to-End Results

Meeting the aim of identifying phishing websites based on the favicon, the end-to-end testing, performed after cleaning up the program and integrating Docker, was performed to ensure the program ran correctly from start to finish. As outlined above, the script does indeed function correctly.

4 DISCUSSION

4.1 GENERAL DISCUSSION

The overall aim of this project was to develop a script that detected phishing sites based on the favicon. Through the completion of six objectives, this was achieved. The objectives are as follows. The program set out to:

- Accept and validate an IP/web address from the user
- Hash the favicon of the given website
- Search the hash on Shodan
- Filter Shodan results to return only suspicious websites
- State whether the given website is likely a phishing site
- Run on any system without manual dependency installation

Concerning the first objective, to accept and validate an IP/website address from the user, the aim for this section was to ensure that the entered address was formatted correctly to be passed into the rest of the program. As found in **Section 3.2 – User Input**, the script meets this goal. The address returned contains no trailing slashes or trailing/leading whitespace and meets an expected format with a valid HTTP(S) scheme. This ensures the address is always passed further into the program in the expected format. This was crucial in meeting the overall aim of detecting phishing sites, as it eliminated the possibility of errors further in the program. If the address was not passed further into the program in the expected format, the *requests* library may not have functioned correctly, which in turn would introduce the possibility of further errors hindering the script from running as expected. The program may have returned inaccurate results or may have crashed completely if it was not made certain that the address is being formatted correctly.

Although this stage of development does meet the required objective, there is room for improvement. The method of testing the favicon's presence is by adding `"/favicon.ico"` to the end of the formatted address. While this is the location that many websites use to store the favicons, this is not the case for every website. If a website does not store its favicon at this address, the program will prematurely exit, as the status code returned will not be 200. To improve this, the program could search further into the website to locate the favicon. Another common way of storing favicons is to use the "favicon" HTML tag which, if located by *PhaviconPhisher*, would allow the program to function with sites that do not store the favicon at `"<address>/favicon.ico"`, in turn allowing more potential phishing websites to be tested by the script.

In terms of the second objective, to hash the favicon of the given websites, it was found that this objective was completed as outlined in **Section 3.3 – Processing URL**, where it was proven that the program hashes the favicon in the Murmur Hash format – the format used by Shodan and therefore the format required to use when invoking the Shodan API. The program downloads the favicon, converts it to base64 to ensure a standard output each time, and then converts this to UTF-8 and hashes it. This process provides consistency and reliability. As shown through testing in **Section 3.3 – Processing URL**, this module returns the correct hash for the given favicon, therefore meeting the objective. This step is fundamental to the

overall aim of detecting phishing websites as it directly influences the results acquired from the Shodan API. If the hash was incorrectly calculated, the results returned from the Shodan API would be incorrect. Even the slightest mismatch would yield drastically different results than expected, causing the final output to be incorrect. This could provide the user with false positives or negatives; thus, it is imperative that the favicon be hashed correctly.

Although this module does successfully hash the favicon, there are some limitations. Firstly, the script can sometimes return a 403 (forbidden) error from a website that should be accessible. This is because some websites are set up to block scripts from connecting to them to protect from attacks such as Denial of Service (DoS)/Distributed Denial of Service (DDoS) (Cloudflare, n.d), where a website gets flooded with traffic to the point where it is brought down. Some websites also block scripts from connecting to prevent web scraping, a process used to automatically extract data from websites. While the script performs as expected with most websites, it is important to note this limitation.

Another limitation of the module is the inability to handle CAPTCHA tests, designed to allow only humans access to a website. Mitigating this is outside the scope of this project, and, as this would likely go against the terms of service of the website behind the CAPTCHA test, this raises significant legal concerns. Therefore, it is necessary to acknowledge that if a website had a CAPTCHA test, this module would not be able to process that website; ergo, the script would not be able to determine whether the website is likely phishing or not.

Focusing on the third objective, to search the calculated hash on Shodan, it was evidenced in **Section 3.4 – Shodan Searching** that the program successfully invokes the Shodan API to search Shodan for the obtained hash. As described in **Section 3.4 – Shodan Searching**, the Shodan API key is stored in an environment variable to ensure security and is retrieved to pass into the API to search for the obtained hash and output the results. The testing implemented shows that the data returned is consistent with what is expected, marking this as a vital segment of the program. Without the correct data being returned, the program may return false positives/negatives. Since the aim of the program is to identify phishing websites by the favicon, this objective must be completed to meet the goal. As the correct results are returned by the API, this objective has been met.

Though the API returns the correct data, there is a major limitation. The Shodan API only allows queries that use search filters (such as the favicon hash) to member or above levels of the API; the free API does not allow this. This means that if a user does not have at least a member-level API key, this section will not work, and thus the program will not be able to search Shodan, meaning that the script will not be able to detect phishing websites using a favicon. However, a Shodan account registered with an academic email address will automatically have access to the member-level API (Shodan, n.d). The member-level API allows searches to be performed with filters, with a limit of 100 searches each month (Shodan, n.d). While this allows the script to function, it does still introduce a limit to the number of uses per month. Although this is outside the scope of the script, it is necessary to note that the number of possible uses is dictated by the level of API registered to the assigned API key.

Turning to the fourth objective, filtering results to return suspicious sites, and the fifth objective, to state whether the website is likely phishing, these objectives directly support the aim of detecting phishing sites based on the favicon. The script tests results returned from the Shodan API against the criteria outlined in **Section 3.5 – Processing Results**, writes all suspicious sites to a file and states to the user whether the given address is likely phishing. As outlined in **Section 3.5 – Processing Results**, this objective was met,

as the filtered results correspond to what was expected after analysis of the raw Shodan API results. The filtering process is essential to the aim of detecting phishing sites using the favicon, as not all sites sharing a favicon with another are malicious. By introducing basic benchmark tests, such as those outlined in **Section 3.5 – Processing Results**, websites likely to be legitimate are filtered out, reducing the number of false positives.

Although this process reduces the number of false positives by filtering out websites that don't meet the set criteria, there is a possibility of a website being flagged as suspicious when it is legitimate. For example, if a legitimate website is running both port 80 and port 443, port 80 may be counted as suspicious due to the lack of SSL, when the website should automatically redirect traffic over port 443. Conversely, due to the static nature of the tests, some suspicious websites may go undetected by the script if it does not meet the specific criteria tested in the script. While implementing a method such as machine learning to more accurately identify advanced phishing websites could be effective, this is outside the scope of this project. The use of the "VirusTotal" API – an API to search VirusTotal, a database website that houses details on files and URLs about malicious content – was considered for this section. However, the free API only allows for four queries each minute (VirusTotal, 2024), which would drastically increase the time taken for the script to run, especially with a very large number of URLs to scan. For this reason, this wasn't included in the script.

In relation to the sixth and final objective set out, to ensure that the script can run on any machine, this aligns with the overall goal of detecting phishing sites based on the favicon by making sure that the script can be run on any system regardless of installed dependencies. The script was integrated with Docker to create a container holding all necessary requirements to run the script, except for the API key. As demonstrated in **Section 3.7 – Docker**, the script was successfully built into a Docker container and runs as expected in this container. This means that users can execute the script without having Python or any dependencies installed, reducing the chance of any errors related to the runtime environment. As mentioned, the only external requirement to run the script in Docker is the API key. This is not hard-coded to allow users to use their own keys and to ensure the security of the original API key.

Overall, the use of PEP8 and PEP257 greatly benefited the project – following PEP8 standards ensured that the variable names adhered to a strict convention for clarity, the indentation was consistent, and the overall structure was easy to follow throughout. The use of PEP257 ensured that the docstrings of each file adhered to a standard format, making the script easier to read and understand. While other Python coding standard conventions exist, such as PEP484 for type hints (van Rossum, et al., 2015), the simplistic nature of the project did not lend itself to any further strict coding conventions. If the program were to be expanded and enlarged, it may be appropriate to use further coding conventions.

As all six objectives set out have been completed, the project successfully met its aim of identifying phishing websites based on the favicon. Each segment of the script was developed and tested to ensure it contributed to the overall goal. While there are certain limitations, such as different favicon locations, websites or CAPTCHA tests blocking the script, reliance on the correct level of Shodan API key, or advanced phishing sites evading detection, the project's core functionality of phishing site detection is operational. As such, the project successfully meets the aim.

The automated detection of phishing sites reduces the likelihood of credentials being stolen through phishing. As outlined in **Section 1.1 – Background**, the top cause of data breaches is compromised credentials (Griffiths, 2025), therefore the script reduces the likelihood of a data breach if it were to be used by employees. As stated in **Section 1.1 – Background**, the expense of a data breach is very high (IBM, n.d). Given the sheer quantity of phishing attacks set out in **Section 1.1 – Background**, a lower chance of compromised credentials would limit the number of data breaches caused by phishing.

4.2 FUTURE WORK

A more expansive project may wish to implement the VirusTotal API. As stated in **Section 4.1 – General Discussion**, the free VirusTotal API tier limits the number of search queries to four per minute, which is unsuitable for this project due to the amount of time it would take. However, if the project were to be expanded or given access to a higher-level tier, the VirusTotal API could provide significant benefits. VirusTotal houses data from a wide range of antiviruses which could be used to find information on given URLs (VirusTotal, 2024). This would enhance the detection rate of the script by finding malicious intent in websites that would not be otherwise detected by the script.

APPENDIX A – PHAVICONPHISHER CODE

Appendix A1 – phavicon_phisher.py

"""

Favicon Phisher - A tool used to detect phishing sites using the favicon.

This script allows the user to enter an IPv4 address or web url, optionally specifying a port.

If the website and favicon can be reached, the script hashes the favicon in murmur hash 3 format and searches the hash on shodan.

The script will return whether or not the website is likely a phishing site based on various criteria such as domain characteristics, non-standard ports, lack of or self-signed SSL certificate, and will output a list of all other suspected phishing sites using this hash.

Functions:

arg_parse(): Parses command line arguments to display the usage information.

display(): Displays ASCII art and developer information.

main(): The entry point of the script.

Developed by Jack Laundon.

Github: <https://github.com/JackLaundon1>

```

"""

```

Results Module. This module filters out and displays the results.

The given IP address is compared against the results,

and a warning message is displayed if the address may be a phishing site.

The rest of the results are output to a text file.

Functions:

add_reason(ip, port, result, reason): adds an IP and reason if appropriate to the dict.

port_test(results): Tests each result from shodan for non-standard ports.

domain_test(results): Tests each result from shodan for a suspicious domain characteristics.

ssl_test(results): Tests each result from shodan for either a missing SSL certificate or a self-signed certificate.

process_results(results, favicon_hash): Calls other functions, outputting the findings to a text file and checking if the provided IP is flagged as a phishing site.

```

"summary": "Some HTTP/2 implementations are vulnerable to a header leak, potentially leading to a denial of service. The attacker sends a stream of headers with a 0-length header name and 0-length header value, optionally Huffman encoded into 1-byte or greater headers. Some implementations allocate memory for these headers and keep the allocation alive until the session dies. This can consume excess memory.",

"summary": "ALPACA is an application layer protocol content confusion attack, exploiting TLS servers implementing different protocols but using compatible certificates, such as multi-domain or wildcard certificates. A MiTM attacker having access to victim's traffic at the TCP/IP layer can redirect traffic from one subdomain to another, resulting in a valid TLS session. This breaks the authentication of TLS and cross-protocol attacks may be possible where the behavior of one protocol service may compromise the other at the application layer.",

"summary": "nginx before versions 1.15.6, 1.14.1 has a vulnerability in the ngx_http_mp4_module, which might allow an attacker to cause infinite loop in a worker process, cause a worker process crash, or might result in worker process memory disclosure by using a specially crafted mp4 file. The issue only affects nginx if it is built with the ngx_http_mp4_module (the module is not built by default) and the .mp4. directive is used in the configuration file. Further, the attack is only possible if an attacker is able to trigger processing of a specially crafted mp4 file with the ngx_http_mp4_module.",

"summary": "nginx before versions 1.15.6, 1.14.1 has a vulnerability in the ngx_http_mp4_module, which might allow an attacker to cause infinite loop in a worker process, cause a worker process crash, or might result in worker process memory disclosure by using a specially crafted mp4 file. The issue only affects nginx if it is built with the ngx_http_mp4_module (the

module is not built by default) and the .mp4. directive is used in the configuration file. Further, the attack is only possible if an attacker is able to trigger processing of a specially crafted mp4 file with the ngx_http_mp4_module.",

```

"summary": "Some HTTP/2 implementations are vulnerable to window size manipulation and stream prioritization manipulation, potentially leading to a denial of service. The attacker requests a large amount of data from a specified resource over multiple streams. They manipulate window size and stream priority to force the server to queue the data in 1-byte chunks. Depending on how efficiently this data is queued, this can consume excess CPU, memory, or both.",

    "summary": "jQuery before 1.9.0 is vulnerable to Cross-site Scripting (XSS) attacks. The jQuery(strInput) function does not differentiate selectors from HTML in a reliable fashion. In vulnerable versions, jQuery determined whether the input was HTML by looking for the '<' character anywhere in the string, giving attackers more flexibility when attempting to construct a malicious payload. In fixed versions, jQuery only deems the input to be HTML if it explicitly starts with the '<' character, limiting exploitability only to attackers who can control the beginning of a string, which is far less common."

"cvss_version": 3.0,

"summary": "In PHP versions 8.0.* before 8.0.30, 8.1.* before 8.1.22, and 8.2.* before 8.2.8 various XML functions rely on libxml global state to track configuration variables, like whether external entities are loaded. This state is assumed to be unchanged unless the user explicitly changes it by calling appropriate function. However, since the state is process-global, other modules - such as ImageMagick - may also use this library within the same process, and change that global state for their internal purposes, and leave it in a state where external entities loading is enabled. This can lead to the situation where external XML is parsed with external entities loaded, which can lead to disclosure of any local files accessible to PHP. This vulnerable state may persist in the same process across many requests, until the process is shut down.",
